Mostly, a positive pregnancy test result means that you are pregnant. When there is a specific amount of hCG (Human Chorionic Gonadotrophin) in your urine, the result comes positive. The hCG is a hormone which is released eight to ten days post-conception when the fertilized egg connects to the wall of the uterus. From this point, the hormone level increases at a steady pace until the next few months.

10 Dogs Sniff Out DiseaseDogs are man's best friend, but we're now learning that they're also a doctor's best helper. The sensitivity of dogs' noses has found them roles in the armed forces, police, and hunting. Able to recognize trace scents at low concentrations, dogs can be trained to alert us nasally blind humans to the presence of a great many things. With bombs or drugs, this ability has long been used, but now hospitals and researchers are employing canine assistants to help with medical

problems.Many diseases cause metabolic changes in the body. This changes the levels of certain compounds or introduces new chemicals to the mix. Doctors rely on these changes when they run blood tests, but said tests often take some time to get results. The ideal test would be one with instant answers. Dogs may be able to supply them. Many of the compounds produced by a diseased body are volatile and can be detected by a nose--more specifically a dog's nose.[1] Dogs have been trained to pick up the scent of various cancers, low blood sugar, and even the approach of seizures.While dogs can smell out illness, don't expect Dr. Fido at your next appointment. They may be sensitive, but training a dog to accurately respond is a time-intensive and expensive process. The canines can also grow bored and stressed if they do not detect a disease in any sample, much like medical students.9 Tasting Urine The tongue is a versatile organ, and before the discovery of accurate chemical analyses, it was one of a doctor's most useful tools. It might strike us as a bit disgusting, but tasting a patient's urine gave their medic an insight into what may have been wrong with them.In 6 BC, a Hindu doctor named Sushruta wrote a description of "Honey Urine," a disease marked by unusually sweet urine. He noted that ants would crowd around it and sampled it for himself.[2] Today, we know that the urine of untreated diabetics contains high levels of sugar. In the 17th century, an English doctor documented the same thing, describing a disease known as "the pissing evil," which caused urine that was "wonderfully sweet as if it were imbued with honey or sugar."The sweetness of a diabetic's urine could also be detected without resorting to tasting it. In one case, it was spotted when sugar crystals were noticed on the black shoes of a patient. They had formed as splashes of urine dried.8 Rabbit And Frog Pregnancy Tests For most of human history, women have generally had to wait many months to discover if they were pregnant. Only with the telling bump of their belly could they be certain. In the early 20th century, that changed with the development of rabbit and frog pregnancy tests.It was found that when a woman is pregnant, her urine would contain a hormone called human chorionic gonadotropin (hCG). Testing directly for this would have been too difficult and costly to be a useful procedure at the time. However, when hCG is injected into a female rabbit, it causes telltale swelling and color changes in the rabbit's ovaries.[3] So a woman's urine would be injected into a rabbit to see if she was pregnant. At first, this required the death of the rabbit to allow the ovaries to be examined, though later, nonlethal methods were found.The rabbit test was soon replaced with the frog test. The African clawed frog would have urine injected into it, too. If the frog produced eggs the next day, then the pregnancy test was positive, as hCG causes the frogs to ovulate.

I can still remember with great fondness and humour when I was sitting in my doctors office, 22 years old, shocked in disbelief that I might be pregnant. 'What more proof do you want', my doctor said, 'You have a positive pregnancy test, you have acne on your chin...' at that point I stopped freaking out for a minute and became really self concious... I replied, 'Oh its just a bit of eczema, I have sensitive skin.' He laughed at me, said it really was a bit of acne. Then it hit me and I realised that this was it. Yes, I was pregnant. And, thanks to that, I had a case of acne, which was just as much of a shock to someone who rarely gets a pimple, let alone acne – and it was clearly obvious to everyone else around me! So here's some information I wish I had when I was a young 22 years old!

Thousands of HIV-positive women give birth every year. Further, because many pregnant women are not tested for HIV and therefore do not receive treatment, the number of children born with HIV is still unacceptably high. What can we do to eliminate this tragic and costly inheritance? In response to a congressional request, this book evaluates the extent to which state efforts have been effective in reducing the perinatal transmission of HIV. The committee recommends that testing HIV be a routine part of prenatal care, and that health care providers notify women that HIV testing is part of the usual array of prenatal tests and that they have an opportunity to refuse the HIV test. This approach could help both reduce the number of pediatric AIDS cases and improve treatment for mothers with AIDS. Reducing the Odds will be of special interest to federal, state, and local health policymakers, prenatal care providers, maternal and child health specialists, public health practitioners, and advocates for HIV/AIDS patients. This test had the benefit of being cheaper than the rabbit test and had easier-to-recognize results. It was the standard pregnancy test into the 1950s.
